

LDS+N Excel Add-in

Reference Guide

LDS+N is an Excel add-in designed to speed the development of solutions using Microsoft Excel by streamlining tasks that are frequently performed by solution developers. By combining the tools into an add-in, features can be added to workbooks without requiring the workbooks themselves to use VBA (Visual BASIC for Applications). That eases distribution of solutions to other users by eliminating the complications inherent with the use of VBA macros in enterprise environments.

LDS+N ribbon

The LDS+N ribbon tab. Left to right: Search, Tables, Selection History, Power Query, and VBA groups.

Reference Guide

Search

Worksheets and Tables (Ctrl-Shift-Q)

Pops up an interactive list of all worksheets and tables contained in the active workbook. The operator can type a few characters to narrow the list and/or select a worksheet or table using *Up/Down* and pressing *Enter*. In workbooks with many worksheets or tables, using this feature is frequently much easier and faster than using the mouse or repeatedly pressing *Ctrl-PgUp/Ctrl-PgDn* to navigate through all worksheets in order.

Row Viewer (Ctrl-Shift-R)

Pops up an interactive list of all values from the current row of a table. Repeated presses of the hotkey cycles through four modes: *navigation* within the worksheet, *searching* row values, *selecting* row values, and *hidden*.

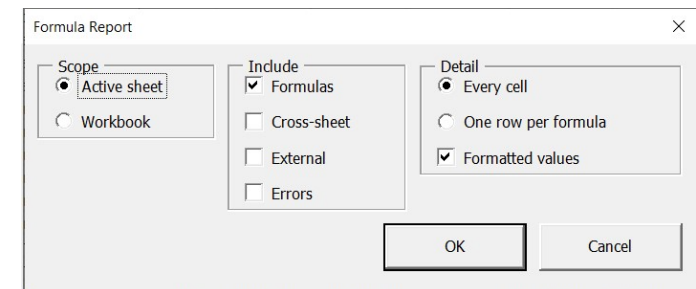

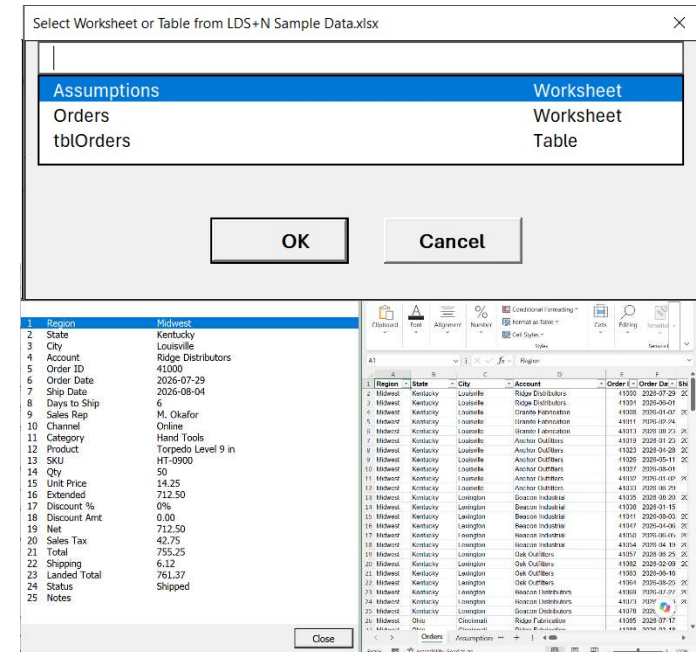

In worksheet *navigation* mode, the list is updated as the operator navigates around the data

In *search* mode, the operator can type a few characters to narrow the list to matching columns or values.

In *selection* mode, the operator can navigate across a row using *Up/Down* without cumbersome horizontal scrolling.

Formula Report (Ctrl-Shift-E)

Generates a report on a new worksheet that documents every formula, cross-sheet reference, external reference and/or error within the active worksheet or the entire workbook. Eases and standardizes the auditing of workbooks.

Reference Guide

Tables

Make Table (Ctrl-Shift-B)

Converts the selected range into a table, and applies common sense defaults (i.e., table style, disables banded rows, freezes panes, and disables gridlines). Individually, none of those operations done manually take much effort, but repeatedly performing them quickly grows tedious.

Format Columns (Ctrl-Shift-M)

Prompts the operator to specify the data type for each table column, records their selections by column name as the defaults for future iterations, applies the most common number formats to each column, and automatically adjusts column widths as narrowly as possible while still accommodating the header and data values. The data type for each column is guessed from column data, so repeatedly pressing *Enter* for each column generally does a good job. In those cases where the default data type is not suitable, it is quick and easy to revise the choices.

Column	Yes	Text	Width
Region	Yes	Text	8.56
State	Yes	Text	10.89
City	Yes	Text	14.44
Account	Yes	Text	22.78
OrderID	Yes	Text	7.56
Order Date	Yes	Date	9.56
Ship Date	Yes	Date	9.56
Days to Ship	Yes	Integer	6.78
Sales Rep	Yes	Text	10.78
Channel	Yes	Text	9.56
Category	Yes	Text	10.44

Upon closing the prompt, the table adjustments are shown interactively as they are applied. The pay-off is realized when the operation is performed again for the same or other tables, as data types specified previously are chosen in advance. Consequently, the operator can frequently accept the default choices and close the form immediately.

Install Dynamic Groups Function

Installs the same dynamic function used by the *Add Group Column* feature. This might be convenient if the operator desires more manual control over the use of the function.

Add Group Column

Prompts the operator to specify the columns by which a table is sorted, adds a hidden helper column to the right of the table that uses an efficient dynamic array function, applies conditional formats that utilize the helper column to reflect breaks between visible row groups based on the specified sort and active filters, and applies dividing lines to highlight group divisions and foreground font colors to highlight repeated values.

Dynamic Groups ? X

Group columns, outermost level first.

Enter column names, numbers, or letters, separated by commas:

1,2,3

Unlike most conditional formats, the highlights survive filtering by the operator. This feature can instantly turn a plain report into a dynamic, useful, and appealing one. The effect sure to elicit good reviews from consumers of the report.

Region	State	City	Account	Order		Days to Ship	
				Order ID	Order Date	Ship Date	Ship
Midwest	Kentucky	Louisville	Ridge Distributors	41000	2026-07-29	2026-08-04	6

Reference Guide

Selection History

Back and Forward (Alt-Left/Alt-Right)

Provides the operator with a browser-like stack of selections through which they can navigate back and forth. Helpful for quickly comparing between values in different parts of a worksheet, or between values on different worksheets or workbooks.

Power Query

Export Queries

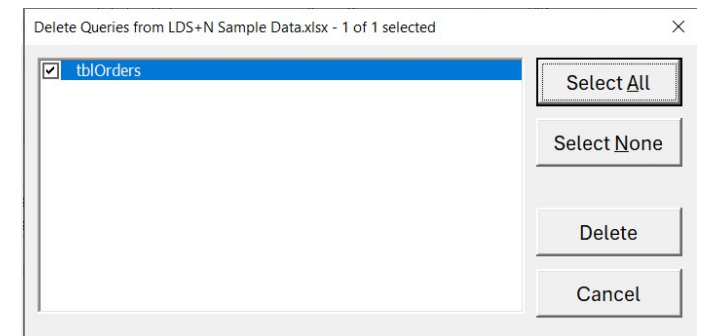

Exports all Power Query queries to a single section document. The single document is well-suited for use with *git*, or for collaborating with AI.

Import Queries

Imports all Power Query queries from a section document or an individual query from an expression document. Revises existing queries in-place and adds new queries to the *Other Queries* group. Queries imported from a section document maintain their names. A query imported from an expression document is named based on the expression document's name.

Delete Queries

Prompts the operator to select queries to be deleted, then deletes them en masse.

Reference Guide

VBA

Export Source

Writes a workbook's entire VBA project out as text, two ways at once.

Every component is exported individually to a `\VBA\` folder adjacent to the workbook file (`.bas`, `.cls`, `.frm/.frx`). Also, one combined file (`<workbook name> Source.txt`) holding every module's verbatim VBE export wrapped in `BEGIN/END FILE` markers, plus a tab-delimited inventory of every form's design-time control geometry, read from the designers so it's identical on any monitor. The combined file begins with a self-documenting header detailing which project it came from, when, a manifest, the full description of the end-to-end export > revise > import process, and the exact format rules (i.e., readable in any text editor). The single `Source.txt` document is well-suited to use with *git*, or for collaborating with AI.

Import Source

Prompts the operator to select an exported `Source.txt` file, then installs each component in place. Form designers and `.frx` binaries are never touched. Missing `.bas/.cls` modules are created. Missing forms are skipped and reported. Members absent from the file are left alone, so a partial file is a targeted patch. The header's *project*: line is checked against the target, and the operator is prompted for confirmation in cases of a mismatch. A summary reports counts of members replaced, created, and skipped.
